

Chapter 1 - Practice Set

Introduction to Python

Write and run each program below as its own separate .py file in VS Code. Everything you need to solve all three questions is in the Chapter 1 notes.

Question 1

Concepts: print() with strings, numbers, calculations, and multiple values

Part A

Print your full name on one line, and your age (as a number, not in quotes) on the next line, using two separate print() statements.

Part B

Using a single print() statement with comma-separated values, print the label "My age in months is" followed by the result of multiplying your age by 12. Do not calculate this yourself - write the multiplication directly inside print() and let Python work it out.

Part C

Print the results of these three calculations on three separate lines, one print() statement each: $100 - 37$, $8 * 8$, and $144 / 12$.

Question 2

Concepts: single-line comments, block comments, commenting out code

Part A

Write a 3-line block comment at the very top of your file. The three lines should describe: (1) what the program does, (2) your name, and (3) the chapter this practice set belongs to.

Part B

Below the block comment, write three `print()` statements that each print a different line of text of your choice. Add a single-line comment directly above each `print()` statement that explains in your own words what that specific line will print.

Part C

Comment out the second `print()` statement using a `#` symbol so it does not run. Run the file and confirm that only the first and third lines of text appear in the terminal.

Question 3

Concepts: bringing it all together - print(), comments, syntax rules, running a file

The Task

Write a single program that acts as a personal introduction. It must satisfy all of the following requirements at the same time:

Requirement 1

A block comment of at least 2 lines at the top describing the program.

Requirement 2

A print() statement that displays your name and the city you live in together on one line using comma-separated values.

Requirement 3

A print() statement that displays a short sentence about your favourite hobby, with a single-line comment above it explaining what it does.

Requirement 4

A print() statement that uses Python to calculate and display your age multiplied by 365, labelled clearly, so the output reads something like: "Days I have been alive: 7300" (replace 7300 with your own result).

Requirement 5

A fourth print() statement of any content you like, commented out with # so it does not run - confirming you know how to disable a line.
